Is multisystem inflammatory syndrome related with coronavirus disease 2019, Kawasaki disease, and angiotensin-converting enzyme 2 in children?

Running Title: MIS-C with COVID-19, Kawasaki disease, and ACE2

Key message
With the coronavirus disease (COVID-19) pandemic, it is important to consider why Kawasaki disease (KD) is prevalent in young children and its symptoms are similar to multisystem inflammatory syndrome in older children. We hypothesized that angiotensin-converting enzyme 2 (ACE2) expression may be related. In fact, this may be an answer why COVID-19 occurs less frequently in children with lower ACE2 expression.
South Korea was one of the first countries affected by coronavirus disease (COVID-19). Due to this rapidly spreading infection, South Korea adopted strict social distancing measures. The government closed schools and private institutions and encouraged people to avoid outings, observe quarantine, and wear masks in public. Correspondingly, the incidence of other viral infections in Korean children in 2020 decreased compared to those reported during the same period in previous years. During the outbreak, severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection was less common and less severe in children than in adults. This may be because children are less frequently exposed to its main source of transmission.\(^1\)

Currently, there are many international reports on children and adolescents diagnosed with multi-system inflammatory syndrome in children (MIS-C), a disease that shows Kawasaki disease (KD)–like clinical features.\(^2\)\(^-\)\(^5\) According to the World Health Organization (WHO), MIS-C can be diagnosed in patients aged 0–19 years presenting with fever lasting for ≥3 days and elevated inflammatory markers, no evidence of other microbial pathogens, and evidence of or exposure to COVID-19. Patients must also have two of the following features: 1) rash or bilateral non-purulent conjunctivitis or signs of mucocutaneous inflammation; 2) hypotension or shock; 3) features of myocardial dysfunction, pericarditis, valvulitis, or coronary abnormalities; 4) evidence of coagulopathy; and 5) acute gastrointestinal (GI) problems.\(^6\)

During the COVID-19 pandemic, children have been less affected than adults in South Korea.\(^7\) However, after the COVID-19 outbreak, patients newly diagnosed with Kawasaki disease (KD) demonstrated a deterioration of biomarkers with evidence of immunocompromise and features of sepsis. This was an unusual form of KD or a form indicating possible KD-like MIS-C with shock. Although it is uncertain whether COVID-19
directly influences this change, it is important to pay careful attention because cases of MIS-C related to COVID-19 in children seem to be on the rise internationally.\textsuperscript{3-6)}

As most MIS-C cases were presented in Europe and the US during the pandemic, rare reports are available of MIS-C in Korea,\textsuperscript{8)} implying that different genetic susceptibilities might play a role in the pathogenesis of MIS-C.

As SARS-CoV-2 infects humans through the angiotensin-converting enzyme 2 (ACE2) receptor, the ACE2 receptor might be among the key factors responsible for vascular involvement in SARS-CoV-2 infection. The affinity of SARS-CoV-2 for the ACE2 receptor may render the vascular endothelial layer susceptible to attack. Patients present with an erythematous rash and vasculitis similar to the clinical manifestations of KD.\textsuperscript{9-12)} Many factors have been associated with both altered ACE2 expression and COVID-19 severity and progression, including age, sex, ethnicity, medication, and several comorbidities such as cardiovascular disease and metabolic syndrome.\textsuperscript{11,12)}

In addition, most MIS-C patients were older than KD patients and presented with GI irritation. Taxonera et al. reported that the presence of coronavirus in the GI tract is associated with greater intestinal inflammation. The ACE2 receptor is a potential link between SARS-CoV-2 infection and intestinal inflammation.\textsuperscript{13)}

Furthermore, Bunyavanich et al. reported that $ACE2$ gene expression was lower in children and higher in adults. Moreover, in younger children, ACE2 expression might develop earlier in the GI tract than in the respiratory tract.\textsuperscript{14)}

Similarly, ACE2 is widely distributed in various human tissues, and many of its determinants have been well recognized; however, ACE2-expressing organs do not equally participate in COVID-19 pathophysiology, implying that other mechanisms are involved in coordinating cellular infection resulting in tissue damage.
With the COVID-19 pandemic, it is important to consider why KD is prevalent in young children and its symptoms are similar to those of MIS-C in older children. It can be hypothesized that ACE2 expression may be related. This might be an answer to why COVID-19 occurs less frequently in children with lower ACE2 expression.

All pediatricians should be aware of all KD-like symptoms or toxic shock syndrome, even in the absence of a confirmed diagnosis of COVID-19, and MIS-C should be considered during the COVID-19 pandemic to ensure proper treatment without the misdiagnosis or overdiagnosis of KD.
